### Results of the 0.0175-Scale Shuttle Orbiter Vehicle Boundary Layer Transition Wind Tunnel Test (MH-11) in the AEDC VKF Tunnel B

**Author Information:** Romere, Paul O.; Campbell, Charles H.; Caram, Jose M.; Bouslog, Stanley A.

**Abstract:** During the flight history of the Space **Shuttle** Orbiter, several flights have experienced earlier than expected laminar to turbulent boundary layer **transition**. Such an experience has often been asymmetric in nature, which results in unplanned control requirements and often higher localized heating. Typically, it was noted that evidence of roughness elements, such as thermal protection system (TPS) gap fillers protruded above the surrounding surface, was generally a common factor for the flights experiencing the unexpected early **transition**. We conducted a test in the **Arnold** Engineering and Development Center's Von Karman Facility Tunnel B at a Mach number of 8.0 and over a Reynolds number range of  $0.6 \times 10^{(sup 6)}/ft$  to  $3.6 \times 10^{(sup 8)}/ft$  to determine the effect of specific discrete roughness element heights and locations on the **transition** of the Orbiter boundary layer from laminar to turbulent at various Reynolds numbers. We limited angle of attack to 35 and 40 degrees, which are most representative of the flight experience. The test used **Shuttle** wind tunnel model 29-0, a 0.0175 scale orbiter model, to which discrete roughness elements of various heights were added at specific locations on the model's windward surfaces, specifically the lower fuselage and wing. Model instrumentation consisted of 55 heat flux gages distributed over the windward surfaces. The major objective of the test was to verify that off-design changes, such as protuberances, to the TPS could cause roughness-induced early transition consistent with flight experience and to determine, at various Reynolds numbers, the size and location of discrete roughness elements what would cause early **transition**. Such test data could then be used for the future development of an Orbiter discrete roughness **transition** model. The results indicated that, while a single roughness element on the windward center line near the nose region could induce early boundary layer **transition** over most of the windward surface, a single roughness element off to the side of the windward centerline could result in a a turbulent boundary layer occurring on a major portion of one side of the windward surface with the other side remaining laminar. Both increasing the height of the roughness element on the windward centerline and cooling the model resulted in boundary layer **transition** at lower freestream Reynolds numbers.

## ABSTRACT

During the flight history of the Space Shuttle Orbiter, several flights have experienced earlier than expected laminar to turbulent boundary layer transition. Such an experience has often been asymmetric in nature, which results in unplanned control requirements and often higher localized heating. Typically, it was noted that evidence of roughness elements, such as thermal protection system (TPS) gap fillers protruding above the surrounding surface, was generally a common factor for the flights experiencing the unexpected early transition.

We conducted a test in the Arnold Engineering and Development Center's Von Karman Facility Tunnel B at a Mach number of 8.0 and over a Reynolds number range of  $0.6 \times 10^6/\text{ft}$  to  $3.6 \times 10^6/\text{ft}$  to determine the effect of specific discrete roughness element heights and locations on the transition of the Orbiter boundary layer from laminar to turbulent at various Reynolds numbers. We limited angle of attack to  $35^\circ$  and  $40^\circ$ , which are most representative of the flight experience. The test used Shuttle wind tunnel model 29-O, a 0.0175-scale Orbiter model, to which discrete roughness elements of various heights were added at specific locations on the model's windward surfaces, specifically the lower fuselage and wing. Model instrumentation consisted of 55 heat flux gages distributed over the windward surfaces.

The major objectives of the test were to verify that off-design changes, such as protuberances, to the TPS could cause roughness-induced early transition consistent with flight experience and to determine, at various Reynolds numbers, the size and location of discrete roughness elements that would cause early transition. Such test data could then be used for the future development of an Orbiter discrete roughness transition model.

Test results indicated that, while a single roughness element on the windward centerline near the nose region could induce early boundary layer transition over most of the windward surface, a single roughness element off to the side of the windward centerline could result in a turbulent boundary layer occurring on a major portion of one side of the windward surface with the other side remaining laminar. Both increasing the height of the roughness element on the windward centerline and cooling the model resulted in boundary layer transition at lower freestream Reynolds numbers.

## INTRODUCTION

This report presents the results of wind tunnel test MH-11, which was conducted in the Arnold Engineering Development Center (AEDC) Von Karman Facility (VKF) Tunnel B during the week of June 5, 1995. The purpose of the test was to determine the effect of specific discrete roughness element heights and locations on the transition of the Orbiter boundary layer from laminar to turbulent at various Reynolds numbers. Three major objectives guided the planning of this test:

- A) Verify that off-design changes to the Orbiter thermal protection system (TPS) can cause roughness-induced early transition consistent with flight experience.
- B) Determine the size and location of discrete roughness elements that will cause early transition.
- C) Use test data to develop an Orbiter discrete roughness transition model.

## TEST FACILITY

The test facility, AEDC VKF Tunnel B shown in Figure 1, consists of a closed-circuit, continuous-flow, variable-density, 50-inch-diameter test section wind tunnel (Reference 1). Through the use of interchangeable axisymmetric contoured nozzles, test conditions at Mach numbers of 6 and 8 are realized. A model injection system allows the model to be removed from the test section while the tunnel remains in operation. Continuous operation of the tunnel with a range of pressure from 100 to 850 psia is possible with air supplied by the VKF main compressor plant. Stagnation temperatures sufficient to avoid air liquefaction in the test section (up to 1,350°R) are achieved from a natural gas combustion heater. Integral external water jackets cool the entire tunnel (throat, nozzle, test section, and diffuser).

## TEST CONDITIONS

The test was run at a Mach number of 8.0 with Reynolds number varying from  $0.6 \times 10^6$  per foot to  $3.6 \times 10^6$  per foot. The model angle of attack was primarily set at 40°, with some data taken at an angle of attack of 35°.

## MODEL DESCRIPTION

The model used in wind tunnel test MH-11 is designated as the Shuttle Orbiter model 29-O and is a 0.0175-scale representation of Orbiter configuration -140B. Figure 2 illustrates the nominal dimensions of the model.

Model 29-O is constructed of stainless steel and is designed to be sting-mounted in the wind tunnel. The model had previously been etched to simulate tiles over the windward surface; however, the model was modified for this test by smoothing the etched simulated tiles to a nominal height of 0.001 inches. For the purposes of this test, the vertical tail and orbital

maneuvering system pods were not included as components of the complete, as tested, wind tunnel model. A total of 48 stainless steel discrete roughness element inserts were manufactured for installation in 11 locations on the model lower surface. The inserts were constructed such that each represented either a smooth surface (zero roughness element height) or a specific discrete roughness element height. Table 1 and Figure 3 define the locations of the inserts and their element heights. Figure 4 presents the geometry of a typical discrete roughness element insert. Each insert was attached to the model surface with two recessed machine screws and the recesses were filled with dental plaster. During the test, the model was configured either with only smooth inserts or with smooth inserts in combination with either one or two discrete roughness element inserts.

## MODEL NOMENCLATURE

The wind tunnel model 29-O dimensions nomenclature is as follows:

b	Wing span, 16.4 inches
BL	$Y_0$ coordinate in model scale (Buttock Line)
L	Reference body length, 22.58 inches
MS	$X_0$ coordinate in model scale (Model Station)
X	Longitudinal body axis
$X_0$	Full-scale Orbiter longitudinal axis coordinate
$Y_0$	Full-scale Orbiter lateral axis coordinate

The model 29-O component nomenclature is as follows:

B17	Fuselage body
C7	Canopy
F5	Baseline body flap
W103	Wing
P	Discrete roughness element insert

## INSTRUMENTATION

### Model Instrumentation

The model was instrumented with 55 coaxial thermocouple or heat flux gages and 4 standard thermocouple gages. The coaxial gages were used to measure the surface heat flux and were made from Constantan wire with a Chromel outer jacket, Figure 5. The gages were 0.0625 inches in diameter. Since the pre-drilled gage locations on the model were 0.125 inches in diameter, 0.123-inch-diameter Chromel sleeves were press fit on the gages. In order to inhibit extraneous thermoelectric emf generation, which can cause errors of up to 25%, as noted by Carl Kidd, et al. (Reference 2), the gages were cemented into the 55 predrilled 0.125-inch holes in the model using Ultrabond 552, a ceramic adhesive. This adhesive has well known high-temperature capabilities; however, for this test, because of the -320°F wall temperature requirement, we performed installation checkouts exposing the adhesive to the LN<sub>2</sub> with no issues encountered. After the gages were cemented into the model, they were smoothed

down flush to the model surface to within a  $\pm 0.001$ -inch tolerance. This smoothing, accomplished by abrading the surface with a light sandpaper, formed the thermocouple junction. Table 2 and Figure 6 define the gage locations.

Four standard thermocouples, Chromel-Alumel, were mounted inside the model to monitor the internal temperatures of the model as a check for model temperature uniformity before each run. The thermocouples were designated as TMOD1 through TMOD4 and were placed on the inside surface of the windward side of the model, along the centerline between coaxial gages 8 and 10, 16 and 29, 37 and 38, and 43 and 46, respectively.

The gages were sampled at 20HZ from start of insertion to 3 seconds after the model reached the test section centerline. However, for data processing, only the data obtained after the first second on centerline were used. We reduced the data using the assumption of a homogeneous, one-dimensional, semi-infinite solid to obtain the heat flux. A previous calibration of the gage material lumped thermal parameter,  $\rho C_p k^{1/2}$ , i.e., (ROCK)<sup>1/2</sup>, was used for the temperature range tested (Reference 3). The maximum heat flux uncertainty was estimated to be 9% and 12% for hot and cold wall, respectively, for heat flux greater than 5 BTU/ft<sup>2</sup>-sec.

## Facility Measurements

The AEDC Facility provided measurements of stagnation pressure and stagnation temperature. These measurements were stated to be accurate to within  $\pm 0.5\%$  and were used to obtain freestream parameters of Mach number and Reynolds number. The accuracy of Mach number and Reynolds number was estimated to be  $\pm 0.3\%$  and  $\pm 1.2\%$ , respectively.

Additional qualitative visual data was provided through the use of a shadowgraph system and oil flows. The shadowgraph system obtained a standard image of the 17-inch window of the test section using 70mm film with a 1-microsecond exposure time. The resolution of the film was 250 lines/inch so that details of the boundary layer could be observed. For the oil flows, the model was painted with metal layout bluing (Dykem), and a silicone oil tinted white with titanium oxide was applied to observe the surface flow streamlines. Videotape coverage was also provided of (1) both forward and aft shadowgraph windows, (2) both top and side direct views of the model, and (3) selected views of the model during cool down in the injection tank.

## LN<sub>2</sub> COOLING FIXTURE

### Fixture Description

AEDC facility personnel designed and constructed a LN<sub>2</sub> cooling system for the purpose of cooling the model lower surface (windward surface) to -320°F before injecting the model into the tunnel test section. The system consisted of an A-shaped manifold, Figure 7, located less than two inches from the model surface, from which an LN<sub>2</sub> spray was directed toward the model surface by a series of holes in the manifold. A truck reservoir trailer located outside the

test facility building supplied the LN<sub>2</sub>, through an insulated line to a series of valves located outside the injection tank. While these valves were used to control the flow of LN<sub>2</sub> to the spray manifold, the system was designed so that gaseous nitrogen (GN<sub>2</sub>) could also be supplied to warm the model and remove frost buildup and to provide a means to pressurize the injection tank. To facilitate the use of the manifold assembly in some future test, the manifold assembly has been packaged with model 29-O, which has been sealed in a special protective packaging utilized for those Shuttle models categorized as "1\*" (the highest category of Shuttle models which are preserved for possible future use), and is stored at the Rockwell International facility in Downey, California.

## **LN<sub>2</sub> Operating Procedures**

One of the issues with cooling the model to -320°F was the frost production on the model. To prevent excessive frost buildup, which affected the transition characteristics of the flow over the model, a set of procedures was developed and modified during the test. These procedures also were aimed at minimizing the amount of time (i.e. minimize the test cost) it took to cool the model to the desired cold wall condition. The procedures were arranged according to what segment of the test was being run and are listed below.

- A) Before cold model runs
  - A1) After the last warm model run, begin flowing LN<sub>2</sub> to the injection tank. This conditions the LN<sub>2</sub> line from the truck reservoir trailer to the injection tank.
  - A2) Conduct general inspection of model or model change.
- B) Continue from above, as well as in between cold model runs
  - B1) At 30 psia before reaching the total pressure test condition:
    - B1a) Start GN<sub>2</sub> flow through the injection tank door nozzle to fill the tank with an N<sub>2</sub> atmosphere \*\*.
    - B1b) Insert model into tunnel to defrost for 6 seconds and remove.
  - B2) Increase injection tank pressure and maintain above the triple point of nitrogen (2 psia) and cycle between 2-4 psia to inhibit icing of the LN<sub>2</sub> spray.
  - B3) Start the LN<sub>2</sub> spray on the model.
  - B4) Stop the GN<sub>2</sub> flow and wait for the model to complete the cool down with the LN<sub>2</sub> spray.
  - B5) Once model temperatures have stabilized at the desired levels, stop the LN<sub>2</sub> spray.
  - B6) Rotate the model to the proper angle of attack, if required.
  - B7) Reduce the injection tank pressure to equalize the pressure across the tunnel door before opening.
  - B8) Inject the model into the tunnel.

C) Repeat runs or test continuation

C1) If a repeat run or a run at a new model attitude, but same condition is needed, return to step B1b.

C2) For a change of conditions, return to step B1a.

D) Model warm-up

D1) Insert model into test section for maximum of 10 seconds' duration. Several injections may be required before the model temperatures are stabilized at the desired level.

\*\* Note that the start of the GN<sub>2</sub> flow was delayed until the model was out of the tunnel and the tunnel floor doors were closed, due to flow disturbances in the test section.

## DATA REDUCTION

### Tunnel Conditions

We computed the tunnel test section freestream parameters using the measured stilling chamber pressure and temperature, and the calibrated test section Mach number. Modifications to account for real gas effects were applied to the equations for a perfect gas isentropic expansion from the stilling chamber to the test section.

### Data Nomenclature

<u>Symbol</u>	<u>Definition</u>
$M_{inf}$	Test section Mach number
$P_{inf}$	Test section static pressure (psia)
$P_0$	Test section stagnation pressure (psia)
$q_{inf}$	Test section dynamic pressure (psf)
$Re_{ft}$	Reynolds number per foot
$Re_L$	Reynolds number based on model length
$T_{inf}$	Test section gas temperature (°R)
$\rho_{inf}$	Test section gas density (slugs/ft <sup>3</sup> )
$\mu_{inf}$	Test section gas viscosity (lbf - sec/ft <sup>2</sup> )
$V_{inf}$	Test section velocity (ft/sec)
$T_0$	Test section stagnation temperature (°R)
$\alpha$	Model angle of attack (degrees)
$G_i$ (i=1,....,55)	Model coaxial thermocouple gage identification number

$X/L_i$ ( $i=1,\dots,55$ )	Axial location of model coaxial thermocouple gage
$2Y/B_i$ ( $i=1,\dots,55$ )	Lateral location of model coaxial thermocouple gage
$Tw_i$ ( $i=1,\dots,55$ )	Model surface temperatures at fifty-five instrumentation locations ( $^{\circ}R$ )
$\dot{q}_i$ ( $i=1,\dots,55$ )	Coaxial thermocouple gage output in engineering units (BTU/ft <sup>2</sup> - sec)
$h_i$ ( $i=1,\dots,55$ )	Local heat transfer coefficients based on $r = 1.0$
$h_{i(0.9)}$	Local heat transfer coefficients based on $r = 0.9$
$h_{ref}$	Stagnation-point reference heat transfer coefficient based on 1-ft scaled radius (Fay-Riddell); see Section 5.5
$h_i/h_{ref}$	Heat transfer coefficient ratio based on $r = 1.0$
$h_{i(0.9)}/h_{ref}$	Heat transfer coefficient ratio based on $r = 0.9$

### Tabulated Values

The quantities listed above in Data Nomenclature were tabulated for each time the data was sampled. The heat transfer coefficients are presented with the application of a recovery factor of 1.0 and 0.9.

### Plotted Data

During the test, at the end of each run, the following plots were electronically displayed for review:

- Plot of windward centerline theoretical (laminar), Reference 4, and data-derived heat transfer coefficients, as derived from gages # 3, 6, 7, 8, 10, 16, 20, 23, 30, 31, 33, 34, 37, 38, 40, 41, 43, 46, and 49. The theoretical heat transfer coefficients, as provided to AEDC by NASA-JSC, are shown in Table 3. An example plot is shown in Figure 8.
- Plot of span-wise theoretical (laminar) and data-derived heat transfer coefficients at an  $X/L$  of 0.3 for the gages # 23, 24, 25, 54, 87, 88, and 89; an  $X/L$  of 0.5 for gages # 34, 35, 53, 93, and 94; and at an  $X/L$  of 0.8 for gages # 45, 56, 66, 70, 75, and 101. Examples of those plots are shown in Figure 8. The span-wise theoretical heat transfer coefficients as provided to AEDC by NAS-JSC, are shown in Table 4.

### ASCII Data Files

An ASCII electronic data file of the quantities listed in Data Nomenclature was generated for each time the data was sampled.

At the end of each test day, the ASCII files for each test run completed were transmitted electronically to NASA-JSC/LESC in Houston, Texas.

## Equations and Methods

As described in Reference 1, the coax gage provides a measurement of the surface temperature of the model, which is assumed to be a homogenous, one-dimensional, semi-infinite solid. For this reason it is important that the thermophysical properties of the gage parts and the test panel material be closely matched. The coax gage heat flux at each instrumented location was computed for each time point ( $t_n$ ) from the measured surface temperature by the following equation derived from semi-infinite solid considerations (Reference 5).

$$QDOT(t_n) = \frac{2(ROCK)^{1/2}}{(\pi)^{1/2}} \sum_{j=1}^n \frac{TW(t_j) - TW(t_{j-1})}{\sqrt{t_n - t_j} + \sqrt{t_j - t_{j-1}}}, \text{ BTU / ft}^2 \cdot \text{sec}$$

where

$j$  = the  $j$ th term in summation,

$n$  = the end point of summation,

$t$  = the elapsed time from liftoff at the start of the inject cycle, sec.

The coax gage surface temperature,  $TW(t_j)$ , was computed by converting the millivolt output to temperature by using a curve fit of the Thermocouple Reference Tables published by the National Institute of Standards and Technology. The temperature dependence of the lumped thermal properties,  $(ROCK)^{1/2}$  for the coax gages was included by means of the following equation

$$(ROCK)^{1/2} = 5.26 \times 10^{-4} \left[ \frac{TW(t_n) + TW(t_i)}{2} \right] + 0.12688, \text{ BTU / ft}^2 \cdot \text{ } ^\circ\text{R} \cdot \text{sec}^{1/2}$$

where

$TW$  = the model surface temperature,  $^\circ\text{R}$ ,

$t_i$  = the initial time at liftoff, sec.

To reduce the effects of any electrical noise in the gage output, the values of QDOT were averaged for fifteen consecutive readings after the test article reached the tunnel centerline. The gage surface temperature was also averaged over the same interval.

The heat transfer coefficient for each gage was computed from

$$H(TT) = \frac{QDOT}{(TT - TW)}, \text{ BTU / ft}^2 \cdot \text{sec} \cdot \text{ } ^\circ\text{R}$$

where

$TT$  = the total temperature.

Since the actual value of recovery temperature is not known at each gage location, we calculated a second value of heat transfer coefficient as follows:

$$H(.9TT) = \frac{QDOT}{(.9TT - TW)}, \text{ BTU / ft}^2 \cdot \text{sec} \cdot \text{ }^\circ R$$

to show the variation over this range of recovery temperature.

In evaluating the Orbiter windward side heating rates, a normalized value must be obtained. We calculated this value using the stagnation point heating to a reference sphere.

One method of calculating the equilibrium stagnation point heat transfer coefficient incorporates the work of Fay and Riddell (Reference 6). This method is widely accepted and has been used in this work:

$$h_{ref} = \frac{8.17173(P_{O_2})^{0.5}(\mu_o)^{0.4}\left(1 - \frac{P_{inf}}{P_{O_2}}\right)^{0.25}(0.2235 + 1.35 \times 10^{-5}(T_o + 560))}{(R_N)^{0.5}(T_o)^{0.15}}$$

where

$h_{ref}$  = Reference heat transfer coefficient based on Fay & Ridell theory

$$\left(\frac{\text{Btu}}{\text{ft}^2 \cdot \text{sec} \cdot \text{ }^\circ R}\right)$$

$P_{O_2}$  = Stagnation pressure *downstream* of a normal shock (psia)

$\mu_o$  = Viscosity based on stagnation temperature  $\left(\frac{\text{lb}_f \cdot \text{sec}}{\text{ft}^2}\right)$

$P_{inf}$  = Freestream static pressure (psia)

$T_o$  = Freestream stagnation temperature ( $^\circ R$ )

$R_N$  = Nose Radius (ft) ( $R_N = 0.0175$  ft.)

This calculation must be performed in relation to the given freestream conditions. The computed reference value is then divided into the obtained Orbiter windward surface heating values ( $h_{local}$ ) for normalization.

To calculate the freestream air viscosity based on stagnation temperature, the Sutherland Law is used (Reference 7):

$$\mu_o = 2.270 \frac{T_o^{3/2}}{T_o + 198.6} \times 10^{-8} \frac{\text{lb} \cdot \text{sec}}{\text{ft}^2}$$

To calculate the stagnation pressure downstream of a normal shock ( $P_{O_2}$ ), one must know specific values for:

- $k$  = Ratio of specific heats ( $c_p/c_v$ ) (Assumed  $k = 1.40$ )
- $M_1$  = Mach number *upstream* of a normal shock (same as  $M_{inf}$ )
- $M_2$  = Mach number *downstream* of a normal shock

With  $k$  and  $M_1$  known, the Mach number downstream ( $M_2$ ) of a normal shock can be found by the relation:

$$M_2 = \sqrt{\frac{(M_1)^2 + \frac{2}{k-1}}{\left(\frac{2k}{k-1}\right)(M_1)^2 - 1}}$$

Now, the following relation can be used to calculate the stagnation pressure downstream of a normal shock (Reference 8):

$$\frac{P_{O_2}}{P_{O_1}} = \frac{M_1}{M_2} \left( \frac{1 + \frac{k-1}{2}(M_2)^2}{1 + \frac{k-1}{2}(M_1)^2} \right)^{\left(\frac{k+1}{2(k-1)}\right)}$$

where

$P_{O_1}$  = Stagnation pressure *upstream* of a normal shock (same as the freestream stagnation pressure -  $P_o$ )

Once these values are obtained,  $h_{ref}$  can be calculated and used to non-dimensionalize the corresponding heat transfer coefficient data.

Given local heat rate information, a value for the local heat transfer coefficient is computed as follows:

$$h_{local} = \left( \frac{\dot{q}_{local}}{r \cdot T_o - T_w} \right)$$

where

$h_{local}$  = Local heat transfer coefficient  $\left( \frac{Btu}{ft^2 \cdot sec \cdot ^\circ R} \right)$

$\dot{q}_{local}$  = Local heating rate  $\left( \frac{Btu}{ft^2 \cdot sec} \right)$

$r$  = Recovery factor (assumed  $r = 1.0$  or  $0.9$ )

$T_w$  = Surface wall temperature ( $^\circ R$ )

Finally,  $h_{ref}$  is divided into  $h_{local}$  to achieve non-dimensionalized heat transfer information.

$$\left( \frac{h_{local}}{h_{ref}} \right)$$

### **Average Surface Temperature**

The ratio of the model temperature,  $T_w$ , to the tunnel stilling chamber temperature,  $T_T$ , necessitated the calculation of an average wall temperature. We obtained this average wall temperature by averaging the values of  $T_w$  for gages 16, 23, and 31. This average value was determined based upon the conditions at the beginning of the injection sequence, before the model had entered the air stream.

### **Measurement Uncertainties**

Instrumentation calibrations and data uncertainty estimates were derived using methods described in Reference 9. Measurement uncertainty consists of a combination of bias and precision errors which are defined as:

$$U = \pm(B + t_{95}S)$$

where  $B$  is the bias limit,  $S$  is the sample standard deviation, and  $t_{95}$  is the 95th percentile point for the two-tailed Student's "t" distribution (95% confidence interval) which for sample sizes greater than 30 is taken equal to 2.

The estimates of the measured data uncertainties for this test, as shown in Reference 1, are presented in Table 5a. The data uncertainties for the measurements are determined from in-place calibrations through the data recording system and data reduction program.

Propagation of the bias and precision errors of measured data through the calculated data was made in accordance with Reference 7, and the results are presented in Table 5b.

## **OPERATIONS**

Installation of the model 29-O, with a sting prebend of 30 degrees, in the AEDC Tunnel B was typically as illustrated in Figure 9 for all testing, except for the oil flow runs. Oil flow runs were accomplished with the model inverted in the tunnel to facilitate photographing the model from a window in the top of the tunnel during the runs. Typically at the VKF Tunnel B, the test model is mounted on the sting support mechanism in the installation/injection tank directly beneath the tunnel test section. This tank is separated from the tunnel by a pair of fairing doors and a safety door. When closed, the fairing doors, except for the slot for the pitch sector, cover the opening to the tank and the safety door seals the tunnel from the tank area. After the model is prepared for a data run, the personnel access door to the injection tank is closed, the tank is vented to the tunnel pressure, the safety and fairing doors are opened, the model is injected into the air stream, and the fairing doors are closed. However, due to the limited time over which data could be taken, the data were taken without closing

the fairing and safety doors. The time required to close the doors would have allowed the model to warm up and violate the uniform temperature assumption. After the data are obtained, the model is retracted into the tank, the fairing and safety doors are closed and the procedures initiated for either a model change or preparation for the next run by either warming or cooling the model. Each injection cycle is termed as a run, and all data obtained are identified in the data tabulations by that run number.

We established the temperature of the windward surface of the model in the injection tank before each run, as previously described. The real-time temperature measurements for selected coaxial gages and the internal model thermocouples were displayed on a video screen to establish when the model reached the desired conditions.

We accomplished the model attitude positioning with the model in the installation/injection tank. As soon as the desired surface temperature was established, the model attitude was set and the model injected into the flow.

The data system was started at first motion of the model, while the model was still in the tank. The time required for the data system to record a single loop of data for each item being scanned, 0.065 seconds, was defined as the data loop period. This process resulted in approximately 15 data loops/second. Both the shadowgraph and the direct videos were initiated at the start of the injection cycle. A single photograph was taken by the 70-mm sequence camera for each test point, after the model was on the tunnel centerline.

For this test, runs were made at a freestream Mach number of 8.0 and Reynolds numbers from  $0.62 \times 10^6$  per foot to  $3.77 \times 10^6$  per foot. The angle of attack was primarily set at  $40^\circ$ , with sideslip set to  $0^\circ$ . A limited number of runs were made at an angle of attack of  $35^\circ$ . The most efficient method to accomplish the test runs was determined using the length of time required to cool or warm the model versus changing Reynolds number. We found it more efficient to run the hot wall runs as a series while changing only Reynolds number and then running the cold wall runs as a series while changing Reynolds number. We also found that the smoothness of the model was very critical for a boundary layer test, as one might suspect. Filling of screw holes and verifying heights of thermocouples were extremely important.

The testing consisted of a combination of hot wall test runs (no cooling of the model before injection into the tunnel) and cold wall test runs (model cooled to  $-320^\circ$  F before injection into the tunnel). The model was cooled by liquid nitrogen,  $LN_2$ , applied to the model windward surface through the use of the  $LN_2$  manifold system, which the AEDC facility personnel designed. The  $LN_2$  cooling caused some problems which affected the test procedures and results. One example involved the dental plaster used to fill the screw recesses. We determined that the model must be near room temperature before applying the plaster, or, following the application of the  $LN_2$  to the model surface, the plaster would tend to either partially or totally fall out during a run. To quickly heat the model to near-room temperature following a series of cooled model runs, we determined that the model should be injected back into the tunnel while the internal thermocouples were monitored. This usually involved several injections before the temperatures stabilized. For future consideration in a test such as

this one, an internal heating element would be beneficial to assist in warming the model in preparation for model changes. We also noticed that frost buildup from the LN<sub>2</sub> cooling process could affect the test results by providing an effective trip to the boundary layer. Again, injection into the tunnel for a short warming period generally solved this problem.

The pretest test matrix was designed to consist of 11 test series corresponding to the configuration of the discrete roughness elements on the model. Each run was to be assigned an alphanumeric designation that would consist of the series identification and run number within the test series. That basic format was

sXrY

where the *X* after the letter *s* provides the series number and the *Y* after the letter *r* provides the run number within the series. For each test series, an alphabetic character was to be added to the test series number (ex.: s2ar3) to distinguish between sets of runs with different roughness element heights or to changes in angle of attack.

Once the test was begun, we quickly determined that it was most efficient to first run all hot wall runs and then all cold wall runs for a given configuration, varying the Reynolds number for each. While still adhering to the test series designation described above, run numbers were also recorded by the usual numeric designation.

Table 6 represents the complete “As-Run Test Matrix.” Each column details the various parameters of the individual run. Column 1 defines the AEDC, or numeric, run number. Column 2 provides the Series number, as was described above. Column 3 is the punch code that is similar to the Series number. Column 4 defines the roughness element used, where an N/A is used to denote the model was smooth with no roughness element. Columns 5 through 10 provide the test conditions of Mach number, total pressure, total temperature, angle of attack, Reynolds number, and ratio of model wall temperature to total temperature. Column 11 denotes whether the cooling system was used. Columns 12 and 13 provide the date and time of the run. Column 14 indicates the delta time between that run and the preceding run, and column 15 contains various remarks that are provided for some of the runs. Note that of the 167 runs conducted during this test, 14 were repeat runs. In the interest of providing as complete a record as possible for future utilization of the results from this test, Table 7 presents the complete test log as recorded by Mr. Jeff Bennett, the Rockwell International test representative.

Near the end of the planned test series, the model was treated with metal layout bluing, Dykem, to provide a dark background in preparation for oil flow runs involving the use of a white titanium oxide and oil mixture. During the runs, the LN<sub>2</sub> system manifold was removed from the work bay and the model was rolled 180° and injected into the flow inverted to facilitate photographing the windward surface with a 70-mm sequence camera mounted in a window on the top of the tunnel test section. The sequence camera took photographs at 2-sec intervals during each oil flow run. The model was cleaned and a fresh application of oil was applied before the next run. The Dykem bluing tended to not remain on the model after the first attempted oil flow run. While several patterns of oil application were utilized in an

attempt to provide the best results possible, the oil was so heavily applied that the resulting oil streamline patterns were adversely affected for most runs.

To assist in documenting all aspects of this test for future use, photographs were taken of the only original model components that were available during the pretest planning. As illustrated in Figures 10 and 11, all that remained of the original model 29-O were the wing/lower fuselage, canopy block, and associated upper wing cover plates.

Installation photographs were taken (Figure 9 and Figure 12, respectively) to document the LN<sub>2</sub> manifold system and its relationship to the model while the model was in the installation/injection tank beneath the test section and of the model positioned for a typical run in the test section.

During the test, multiple shadowgraphs were taken for each run. These were a post-test product which was delivered as a set of 70-mm negatives and a corresponding set of contact prints.

## **DATA PRESENTATION AND RESULTS**

### **Overview of Test Data**

We conducted a total of 167 runs during this test program. Of these, 5 runs (# 145 - 149) were oil flow runs and no heat flux data were obtained. For 27 runs (#1-13, 38, 41, 43, 46, 47, 49, 55, 82, 91, 115, 127, 136, 166, 167), data were not obtained or the data were corrupted due to unintentional roughness. For 18 runs (# 15, 17, 19, 22, 34, 86, 101-108, 130-132, 135) excessive frost was observed on the model due to the LN<sub>2</sub> cooling. Therefore, we obtained good heat flux data that can be used to evaluate the desired transition effects for 117 runs. Table 8 presents a summary list of these runs organized by configuration (smooth body or roughness element installed). Table 9 presents those runs which were deemed faulty and were not used.

### **Shock Interference Effect**

Initial runs of the test matrix exhibited unexpected, repeatable turbulent-level heating past the  $X/L = 0.75$  location. We believed this phenomenon to be due to transition on the model when the higher Reynolds numbers were run. However, the freestream conditions were decreased such that laminar flow was expected and yet, the heating at the aft of the model continued to be high. We realized that something was forcing the heating to approach turbulent levels at the rear of the model regardless of the freestream conditions.

As part of the regular matrix of conditions, we planned a set of lower angle of attack, as well as inverted model, test points. Upon lowering the angle of attack to 35°, the heating at the aft end of the model for the lower Reynolds numbers approached laminar levels. The same was seen for both the 40° and 35° cases when the model was inverted, thereby verifying that

something was forcing the boundary layer to be turbulent toward the aft end of the vehicle for 40° angle of attack in the non-inverted configuration.

Investigation of the temperature time history plots for a number of centerline thermocouples revealed that, as the model was approaching the centerline of the tunnel, the thermocouples indicated a step increase in temperature sequentially down the vehicle for both angles of attack, and for both the inverted and normal model orientations. This effect was attributed to a stationary shock that the model passed through during insertion into the tunnel, which would also cross each thermocouple sequentially from nose to tail.

We investigated two plausible explanations for the existence of a shock in the tunnel. The first involved the reflection of a shock wave from the pit beneath the model. The second explanation was the formation of a tunnel wall boundary layer induced shock upstream of the model. Shock reflection from the pit was deemed unlikely because of the model positioning with respect to the tunnel, and the effect seemed to be stationary as the model approached the tunnel centerline. The formation of a boundary layer induced shock could be explained, however. Since the heat transfer tests being performed had very short on centerline times, the insertion doors were not being closed during a data point. The process for a model insertion involved opening the insertion doors, inserting the model for the required duration, returning the model to the pit, and finally closing the insertion doors. The fact that the insertion doors remained open during the time the model was on centerline opened the possibility to a disturbance in the pit feeding forward in the tunnel wall boundary layer. The most likely scenario involved the formation of a separation bubble pair in the pit, and in the upstream tunnel boundary layer. The formation of a small separation bubble in the upstream boundary layer on the tunnel wall would cause the formation of a shock emanating from the beginning of the separation bubble.

A tunnel survey of the Mach 8 test section flow field had been performed in August and September of 1991; however, no data were taken with the insertion doors open. A similar survey of the Mach 6 test section was performed with the insertion doors open and closed in 1974, and the existence of a tunnel wall boundary layer induced shock was documented for the open-door configuration (Reference 10). This Mach 6 tunnel survey identified a disturbance in the flow field which appears to originate ahead of the open cavity door (Figure 13). The angle of the disturbance relative to the tunnel centerline can be expected to differ in the Mach 8 facility. Although similar data for the Mach 8 facility does not exist, the results of this test demonstrate the existence of a similar disturbance. The Mach 6 test section survey thereby validates the aforementioned explanation of the higher than expected temperatures on the aft end of the model, and the existence of a disturbance like that shown in Figure 13 would explain the spatially sequential, step increase in thermocouple readings during model insertion.

The correction for runs after run 107 involved repositioning the model in the tunnel, above the location of the boundary layer induced shock. Figures 14 and 15 illustrate the original and revised model positions. Table 8 includes a column that indicates whether this problem was present during a particular run.

## Smooth Body Transition Data

### *Effect of Reynolds Number*

During this test program, test data were obtained for freestream Reynolds numbers from  $0.6 \times 10^6$  per foot to  $3.6 \times 10^6$  per foot. Figure 16 presents the effect of the variation of the freestream Reynolds number on the smooth body transition for the centerline of the model. Recall that the smooth body included a distributed roughness of 0.001 in. on the windward surface. At the highest Reynolds number ( $3.58 \times 10^6$  per foot), the transition front is located at approximately  $X/L = 0.4$ . As the freestream Reynolds number was decreased, the transition front moved further back on the model toward the tail. At Reynolds number =  $1.52 \times 10^6$  per foot, we observed mostly laminar flow on the model. However, near the tail end of the model there is a slight increase in heating that may be due to near-transitional heating. Figures A-1 through A-5 in Appendix A provide comparisons of the measured heat transfer coefficients to the theoretical laminar values for the entire windward surface. The base color contours represent the predicted laminar heating, and the colors within the circles correspond to the heating levels measured by the heat flux gages. When the colors within the circles nearly match the surrounding color, then laminar flow is indicated. When the color within the circle indicates higher heating levels than the surrounding colors, then transitional to turbulent heating levels are indicated. These plots provide a more complete description of the transition front on the model windward surface.

### *Effect of Angle of Attack*

Figure 17 presents the centerline heat transfer data for two Reynolds numbers ( $3.58 \times 10^6$  and  $1.52 \times 10^6$  per foot) at  $35^\circ$  and  $40^\circ$  angle of attack. The centerline data indicate that an angle-of-attack change from  $35^\circ$  to  $40^\circ$  has little effect on the transition location and both cases appear to experience transitional heating at the tail-end of the model for the lower Reynolds number. However, the color contour plots presented in Figures A-1, A-5, A-6, and A-7 in Appendix A indicate that the transition front has moved further forward on the wing for the  $40^\circ$  case than for the  $35^\circ$  case.

### *Effect of Wall Cooling*

Figure 18 presents the centerline heat transfer data for two Reynolds numbers ( $3.58 \times 10^6$  and  $2.50 \times 10^6$  per foot) and two average wall temperature ratios ( $T_w/T_0=0.37$  and  $T_w/T_0=0.13$ ). At the higher Reynolds number, the cold wall case results in a significant jump forward of the transition front to approximately  $X/L = 0.2$  as compared to  $X/L = 0.4$  for the warm wall case. Furthermore, for the cold wall case, the transition process from laminar to turbulent occurs across a shorter distance. For the lower Reynolds number,  $2.5 \times 10^6$  per foot, the transition front is at approximately  $X/L = 0.55$  for the warm wall and at  $X/L = 0.35$  for the cold wall. Again, turbulent levels of heating are attained more rapidly for the cold wall case. Figures A-1, A-3, A-8, and A-9 in Appendix A provide the corresponding color plots for these cases. The change in wall temperature results in a dramatic change in the transition location. At the

high Reynolds number (Figure A-8), it is unknown why the transition front appears to be located further upstream on one side of the model than the other.

## **Roughness Element Transition Data**

### ***Effect of Reynolds Number***

Figure 19 presents the resultant heat transfer distributions on the model centerline with a 0.008-inch roughness element located at Location D. At the highest Reynolds number,  $2.51 \times 10^6$  per foot, transition occurs at the roughness element, and turbulent levels of heating are attained rapidly. By decreasing the Reynolds number to  $2.05 \times 10^6$  per foot, transition still occurs at the element. But after an initial increase in heating, turbulent heating is attained considerably further downstream. As the Reynolds number is further decreased to  $1.49 \times 10^6$  per foot, the initial increase in heating is less and the transition to turbulence is moved even further downstream. At a Reynolds number of  $0.998 \times 10^6$  per foot, a small disturbance in the heating near the element is noticed but the rest of the model appears to be laminar. Figures A-5, A-10, A-11, A-12, and A-13 in Appendix A present the corresponding contour plots.

### ***Effect of Angle of Attack***

Figure 20 presents the centerline heat transfer results for a 0.015-inch roughness element located on model centerline at Location G. Three runs were made with a Reynolds number of  $1.0 \times 10^6$  per foot for  $40^\circ$ ,  $38^\circ$ , and  $35^\circ$  angle of attack. For all three cases, the transition location is at the element and for  $40^\circ$  and  $38^\circ$  little difference in the results are observed. However, at  $35^\circ$  the distance between transition onset, at the element, to full turbulence is slightly delayed. The color plots presented in Figures A-14, A-15, and A-16 in Appendix A show that the effect of the roughness element is restricted to the center area of the model downstream of the element.

Figure 21 presents the centerline results for a roughness element located off-centerline at Location C for a Reynolds number of  $2.0 \times 10^6$  per foot. Results for two roughness heights—0.008 and 0.015 inches—and for  $35^\circ$  and  $40^\circ$  angle of attack are presented. For both heights, the roughness elements appear to have little affect on the model centerline heating at  $40^\circ$  angle of attack. However, at  $35^\circ$  the smaller roughness element results in the transition front crossing the centerline at approximately  $X/L = 0.5$ . Referring to the color plots in Figures A-17, A-18, A-19, and A-20 in Appendix A, you can see that both roughness elements have a greater influence on transition at the lower angle of attack and that the smaller roughness element has more of an affect than the larger one. These phenomena will require further investigation.

Figure 22 presents the centerline results for a 0.015-inch roughness element located off-centerline at Location F for a Reynolds number of  $2.0 \times 10^6$  per foot for both  $35^\circ$  and  $40^\circ$  angle of attack. No affect on transition is observed on the centerline. However, Figures A-4, A-21, A-22, and A-23 in Appendix A indicate that at  $35^\circ$  the roughness element has more affect on transition off-centerline than for the  $40^\circ$  case.

### ***Effect of Wall Cooling***

Figure 23a-c compares the centerline heat flux results for a warm wall and cold wall model with a 0.008-inch roughness element at Location D. As shown in Figure 23a for a Reynolds number of  $2.0 \times 10^6$  per foot, the wall temperature had a significant effect on transition on the smooth body. However, for the case with the roughness element, transition occurred at the element for both wall temperatures, and the rise to turbulent heating has similar trends. Similar trends are observed at a lower Reynolds number of  $1.5 \times 10^6$  per foot (Figure 23b). At a Reynolds number of  $1.0 \times 10^6$  per foot (Figure 23c), both the smooth model and the model with a roughness element have mostly laminar heating for the warm wall case except for a slight increase in heating just downstream of the roughness element. For the cold wall case, both model configurations have heating levels slightly higher than laminar on the aft half of the model, which may indicate transitional heating. Figures A-11, A-24, A-25, and A-26 in Appendix A provide the contour plots for a Reynolds number of  $2.0 \times 10^6$  per foot. Figures A-12, A-27, A-28, and A-29 present the contour plots for a Reynolds number of  $1.5 \times 10^6$  per foot. Figures A-13, A-30, A-31, and A-32 present the contour plots for a Reynolds number of  $1.0 \times 10^6$  per foot.

### ***Effect of Roughness Element Height***

At Location A on the model, two roughness element heights were tested—0.004 and 0.008 inches. At a Reynolds number of  $2.0 \times 10^6$  per foot (Figure 24), transition occurs on the smooth body at approximately  $X/L = 0.6$ . The small roughness element brings the transition front forward to approximately  $X/L = 0.4$ . The large roughness element causes transition to occur at the element. Figures A-4, A-33 and A-34 in Appendix A present the contour plots for these cases.

At Location G on the model, two roughness element heights were also tested—0.006 and 0.015 inches. For a Reynolds number of  $1.5 \times 10^6$  per foot (Figure 25), the largest roughness element brings transition to the element; whereas the small roughness element has little effect on transition when compared to the smooth body results. Figures A-5, A-35, and A-36 present the contour plots.

### ***Effect of Roughness Location***

With a 0.005-inch roughness element at Location E and a 0.006-inch roughness element at Location I, little effect on transition on the model centerline was observed for a Reynolds number of  $2.5 \times 10^6$  per foot (Figure 26). However, the color plot in Figure A-37 indicates that the roughness element at I brings transition to the element, but the element at E has no apparent effect on transition.

A 0.010-inch and a 0.008-inch roughness element were tested simultaneously at Locations J and K, respectively. As shown in Figure 27, the transition front is located at element J for a Reynolds number of  $1.5 \times 10^6$  per foot. Reviewing the color plot in Figure A-38, element K also brings the transition front to the element. In both cases, the effect of the elements appears to be restricted to a narrow region downstream of the element.

## **Oil Flow Data**

Oil flows were run at both 35° and 40° angle of attack. Several patterns of titanium oxide and oil mixture applications were utilized in an attempt to provide the best results possible. However, in most cases, the oil mixture was so heavily applied that the resulting oil streamline patterns were not of the best quality. The Dykem bluing, used to provide a dark surface background for the white titanium oxide and oil mixture, tended to not remain on the model after the first oil flow attempt. The last three oil flow runs (147, 148, and 149) were of an acceptable quality. Additionally, roughness element C-4 was installed on the model for these runs. The results of runs 147 and 148 at angles of attack of 35° and 40° are presented in Figures 28 and 29, respectively. The higher shear due to turbulent flow on the model's right side is evident in the photos.

## **Shadowgraph Data**

During each test run, a shadowgraph was obtained of the Orbiter model in the test section. These profile photographs show clearly the bow shock around the model. Details of the boundary layer state—laminar or turbulent—are not discernible from the photographs. Due to the sheer number of photographs involved, only Figures 30 and 31 (Runs 27 and 37) are presented as examples of the shadowgraphs taken. Run 27 was a smooth-body run and the boundary-layer was mostly laminar. During Run 37, the model had a 0.008-inch roughness element on the model centerline at  $X/L \sim 0.05$  and resulted in a turbulent boundary layer for most of the body.

## **Plotted and Tabulated Data**

Appendix B and Appendix C contain the plotted and tabulated data for the test. Data from runs 2, 3, 11, 12, and 38 were not recovered. Appendix B, the plotted data, includes both the data obtained along the model centerline and the span-wise distributions at three axial locations,  $X/L = 0.3, 0.5,$  and  $0.8$ . The plotted heat flux gage data are compared to the computed laminar heating levels.

## **CONCLUSIONS**

Heat flux data have been obtained on the windward surface of a 0.0175-scale Orbiter model at a Mach number of 8 and over a Reynolds number range of  $0.6 \times 10^6$  to  $3.6 \times 10^6/\text{ft}$ . Single rectangular roughness elements were positioned on the model at nine different locations to evaluate the effect of discrete roughness on the boundary layer transition. From the test results, the following conclusions can be drawn:

- A) A single roughness element on the windward centerline in the nose region can induce early boundary layer transition over most of the windward surface.
- B) A single roughness element off to the side of the windward centerline can result in a turbulent boundary layer occurring on a major portion of one side of the windward surface while the other side remains laminar.

- C) Small changes in angle of attack (5 degrees) have little effect on transition for a smooth body or for roughness elements located on the windward centerline. However, for off-centerline roughness elements, the transition trends are affected by angle of attack.
- D) Cooling the model results in boundary layer transition occurring at lower freestream Reynolds numbers.
- E) Increasing the height of roughness elements located on the windward centerline results in transition at lower freestream Reynolds numbers. However, the trend is less obvious for the off-centerline elements.
- F) Roughness elements located further aft on the model result in only narrow regions of turbulence on the model.

44	204	A-3	7.90	330	1289	40	1.5	Cold	on	22:25	0:20	TDP = -24
45	206	A-3	7.86	207	1244	40	1	Cold	on	22:40	0:15	TDP = -19.3
46	1301	D-3	7.97	575	1320	40	2.5	Warm	off	23:13	0:33	Model Change #2, Waited on Data, Run Good
47	1301	D-3	7.97	575	1320	40	2.5	Warm	off	23:16	0:03	TDP = -28, Model was not isothermic

Comments: On Run #33, started deicing/ cooling of model 40 psia before the test condition was reached. Model was ready with plenty of time.  
On Run #34, modified procedure to start 30 psia before condition reached w/ no deicing; results no good, deicing req'd.  
Run #43 was not a run.

Test Title: NASA MH11

AEDC - Orbiter Transition Test  
Run Log

page 2 of 2

Test Model: Orbiter 29-O

Date: June 7, 1995

Run	Punch Code	Element	Nom. Mach	Po psia	To °R	Alpha °	Re/ft	Tw/To	Cooling System	Clock Time at Liftoff	Delta Time minutes	Remarks
48	1301	D-3	7.94	575	1320	40	2.5	Warm	off	23:23	0:07	R#47, TDP = -27
49	1303	D-3	7.94	460	1321	40	2	Warm	off	23:35	0:12	TDP = -22.3, Stopped here due to TDP problems

Comments: Run #47 had questionable wall temp, particularly on nose gage #3 (= 95°F)  
Run #46, data was recovered but recommend using Run #48 as best of Run 46-48 series.

Comments: Run#8031 and after: Model center of rotation changed from 20" forward of the tunnel Aft. C.R. (STA. 29.673, see installation figure) to 10" forward. This raises the model higher into the test section to avoid tunnel wall separation shock. Also, model was painted blue with Dychem for upcoming oil flows. Recommend to wait on paint until needed, Dychem may be causing additional icing problems.

167	2321	G-2	?	100	1040	40	?	Warm	off	1:48	0:08	Extra run at low Re., See Comments

Comments: Run #165: time temperature run at original model rotation point; looking for separation shock interference.  
 Runs #166 & 167 were special runs at different plant conditions to check flow.  
 Run 166 may have usefull data but 167 had an unstable shock.

## Table 7. Wind Tunnel Test Log

### Monday June 5, 1995

**8:00 AM** - Arrived at Tunnel B after getting Badge at Security. Met with Ken Nutt (x7740) and Joe Donaldson (x7760) who conducted a tour of facility. Model 29-O is installed in the tunnel and work is continuing on the manifold which will be delivering the liquid nitrogen used for cooling the model. This is proceeding well and a test will be run at approximately 1:00 PM to evaluate its effectiveness.

**9:00 AM** - Met with Carl Kidd to run dunk test on one of the extra thermocouples. This test was requested by Joe Caram due to the unusual design (using sleeves surrounding the thermocouple. The concern is that because the sleeves are actually glued to the model and not the thermocouple, the extreme cycling of temperature could dislodge the thermocouples. The extra thermocouple, (identical to those in the model) was glued to a 1/4" plate of steel with the electrical leads attached to a meter which displayed temperatures in degrees Fahrenheit. This assembly was submersed in liquid nitrogen until the temperature was -320 ° F. It was then taken out and allowed to warm to room temperature. The accuracy of the reading was checked and the gage was examined as to whether it had shifted or become dislodged. This procedure was repeated several times. One iteration included the use of a heat gun to more closely simulate test conditions. The gage showed no sign of becoming dislodged and the readings were consistent. This test took approximately 1 hour.

**10:00 AM** - Ken Nutt informed me as to the current status of the test. Facility requirements dictate that we will not be blowing air until at least 10:00 AM each day. On Wednesday & Thursday, the test will begin later. Due to a 10 hour per day schedule, several very late nights will be required to complete the test. There is some concern that hurricane Allison (the edge of the storm may hit here) may increase the chances of frost on the model during the test. Due to the need to complete the nitrogen manifold system, fit checks of the roughness elements may not be made until Tuesday morning prior to the start of the test.

**12:45 PM** - In preparation of the first test of the Liquid nitrogen cooling system, the first configuration roughness elements (all smooth) were installed. Each was checked as to whether the number (marked on one side) or letter (marked on the other side) faced forward. In all cases, the letter (which designates the roughness element location) faced forward. Others will be checked as time permits, but it will be assumed that the letter A - K will face towards the nose.

**1:15 PM** - Ken Nutt informed me that earlier in the day, continuity checks were made and all data from the thermocouples is correct. The User Room phone number is x6153. The designated test number for this test (AEDC's number) is 2573.

**2:20 PM** - Tunnel pumped down to 0.789 psi, much better than expected (<2.0 psi). Began spraying the model with liquid nitrogen. Model is partially visible and began frosting up after several minutes of spraying. Gages 3, 8, 16, 23, 34, 38, 41, 46, 49, 25, 53, 54, 56, 75, 87, 93, 95, & 101 were visually monitored during test. These gages can be viewed during each run on video

### **Table 7. Continued**

monitors. During this test most of the gages achieved temperatures of approximately -300 ° F. Some in the area of x/c of 0.65+ showed temperatures of -150 ° F. All gages appeared to record reasonable temperatures. Data system is currently not functioning. The problem is being analyzed and should be resolved soon.

**2:42 PM** - The test was ended and the model was very frosty looking on the entire lower surface and up onto the sides. Ken Nutt and Joe Donaldson have recognized the need to more evenly cool the model. Currently, the length of time to cool is too long and that time results in the frost. Changes are being made in the manifold to cool the aft portion of the model more effectively.

**3:09 PM** - The test section was opened and the model examined. The model looks good and no problems are apparent with either the roughness elements of the thermocouples. Various plans are being discussed as to the best way of resolving the variance in cooling different areas.

**3:35 PM** - Corrective action is now being taken to minimize the cooling issue previously discussed. A shift will be working late tonight drilling extra holes and expanding others in the manifold in the area in question. Tomorrow another test is scheduled along with data system checkout prior to the start of the test.

### **Tuesday June 6, 1995**

**8:00 AM** - Arrived at Tunnel B and inspected the model. The holes on the center part of the liquid nitrogen cooling manifold have been opened up from 0.040" to 0.060" dia. Additional holes have been drilled in the rear horizontal pipe. Pressure has been increased from 25 to 35 psi. All these changes are efforts to equalize temperature cooling. The rest of the ABLT analysis team has arrived at tunnel B. The members are: Joe Caram - NASA/JSC, Chuck Campbell - NASA/JSC, Paul Romere - NASA/JSC, Stan Bouslog - Lockheed, Scott Berry - NASA/LaRC, and Col. Ken Stetson - USAF Ret.

**9:30 AM** - Screw holes on model filled with the plaster compound, all look smooth. Model is ready for first run.

**10:40 AM** - Tunnel pumped down to 0.703 psi.

**10:53 AM** - Tunnel on conditions.

**11:19 AM** - Model inserted to check startup loads @ 230 psi. Shock looked solid and no problems occurred.

**11:23 AM** - Cooling system started, aft areas appear to be cooling more evenly than yesterday. Frosting problems again are occurring and AEDC is playing around with various parameters to find a way to minimize frost. Increasing tank pressure to 4+ significantly reduced the frost.

### Table 7. Continued

**12:30M** - One of two heaters is not functioning, AEDC is attempting to solve the problem. A test was made to see if an injection could be made with the nitrogen system on. The safety doors were frozen and could not be opened. This may be due only to the length of time the nitrogen system has been on (1 hr 18 min). Visual inspection of model showed that all plaster remained in the screw holes.

**12:51 PM** - Started nitrogen system in preparation for first test point. Heater failure resulted in shutdown of cooling system.

**2:11 PM** - Started nitrogen system again in preparation for first test point. Injected model at 2:28 PM. No frost appeared on lower surface. Run #1 Punch Code: 0002.

**3:00 PM** - Discovered what appeared to be 2 t/c plugs on the right outboard wing which had fallen out. We went into the tunnel and examined the model and discovered that what was seen was actually the bottom of the upper panel screws. No changes were necessary or made. A decision was made to make all non-cooled runs in a row because it is a more efficient way of running the test. We will make a series of cold wall tests with the same configuration. Varying Reynolds number is faster than cooling/heating.

**4:00 PM** - Gage #34 is failing, temperatures are fluctuating + or - 50 ° F before injection. When we get a chance, this gage will be sanded in an effort to fix the gage. Currently we are averaging approximately 20 min. between runs. Also the transition is not moving aft on the centerline and is fixed at  $X/L = 0.40$ . There may be a protuberance ahead of gage #31. Roughness element "G" is directly in front of this gage, there also could be a tile height that is excessive. At the next opportunity we will inspect and change if necessary the area.

**5:30 PM** - Sanded gage #34 and it is working again. Sanded #23 (which was hanging slightly into the flow) and several screw fillers. It appears that model parts are moving around and the possibility exists that the t/c's are dropping into the flow. We will need to monitor these on a regular basis.

**6:00 PM** - Began series using cooling system. Runs are similar to all previous except for cooling.

**6:10 PM** - Made a repeat run of #5 (No cooling,  $Re/ft = 3.0$ ,  $Po = 710$ ). Confirmed that the fixes to the model worked. The transition issue has been dramatically improved. Data was very different in the  $X/L = .4$  area. At this time 15% of Phase I is complete and 6.2% of the total test is now complete.

**7:32 PM** - Currently we are making 2.8 runs per hour. Most effective method of using the cooling system and minimizing amount of nitrogen used is to leave nitrogen off during Reynolds Number changes and then inject the model for a short time to eliminate the frost build up. Then cool again followed by the true injection. This method is working well.

## **Table 7. Continued**

**9:23 PM** - We have completed the first series of runs in Phase I. We are now going to repeat hot runs that had the protuberance problems described at 4:00 PM to see whether the transition point moves more predictably with Reynolds Number. We will plan for the first model change in the morning. E-1 will be replaced with E-2 and I-1 will be replaced with I-2.

**10:11 PM** - End of run day #1; 27 runs @ 3.07 runs/hr. 25% of Phase I is complete and 10.27% of original Run Matrix is finished. We will begin tomorrow with a model change described above and check model in the X/L area for possible protuberances.

### **Wednesday, June 7, 1995**

**10:30 AM** - Inspected and sanded several t/c's which were hanging down below the OML. These included: #8, 10, 16, 23, 33, 34, 37, 40, 46, 54, 87, 88, & 92. Element AB was also sanded. A 0.0015 feeler gauge was obtained to measure the actual heights of t/c's as they move. It appears that t/c's are moving slowly out of the model. We will attempt to find the source of the problem. This inspection / sanding effort took approximately 1 hour.

**11:48 AM** - Elements E1 and I1 were replaced with E2 & I2, respectively. Again, the letter designations face forward for these elements. Also, screw holes for elements A, B, C, D, F, J & K were refilled with dental plaster. Left hand inspection cover screws that were an issue yesterday were removed and positions swapped. This solved the depth issue. It was noted that the lower right plug in the right hand side inspection cover is loose, we will monitor. This model change took 42 minutes to complete.

**12:30 PM** - Photos of the model and facility were taken and took 45 minutes. Details included cooling system from tanks to manifold, model injected and several tunnel related photos.

**2:30 PM** - Nitrogen cooling manifold was moved closer to model by 3/8" and re-angled to match model angle. The hope is that cooling will be faster due to the distance from the rear of cooling manifold to aft of model.

**4:00 PM** - Tunnel coming on-line. Hot runs of Series 2 of Phase I will be run first. 4 runs will be made and then we will inspect the model and this will be followed by the cool runs.

**5:22 PM** - First run of shift.

**7:22 PM** - Frost build-up tripped flow (Run #34). Will repeat this run. The repositioning of the cooling manifold has improved the time required to cool the model. Rear temperatures drop faster than before.

**7:42 PM** - Started model change, changed E2 and I2 to E1 and I1 (Smooth body). A3 was installed in place of A1. The entire model was checked and showed that none of the t/cs had moved. The change took 22 minutes and required a heat gun to allow dental plaster to be put in

### Table 7. Continued

screw holes. It is necessary to either spend more time in tunnel heating model or use heat gun to eliminate frost prior to change. It would be beneficial if an internal heater was used to heat the model following a cold run prior to model change.

**8:19 PM** - Dental plaster smeared on nose (Element A3). The thickness was negligible and was wiped away.

**9:30 PM** - Refilled screw hold of element A. We are planning to run till 2:00 AM. Currently problems in recording test data is holding up test. For this shift we are getting approximately 3.5 runs/hr and 23% of the test (as planned) is complete.

**10:50 PM** - Made 2nd model change, replaced A3 with A1 and replaced D1 with D3. The change took 15 minutes. The model looked good and nothing seems to be moving around.

**11:45 PM** - Problems with heaters has forced an end to the testing for now. 21 runs were completed with a run per hour ratio of 3.4 runs/hr. 26% of the original test matrix is now finished.

#### Thursday June 8, 1995

**10:00 AM** - Made a detailed inspection of model, nothing appears to be moving around. Discussions as to what runs will be made today. We will continue on the Phase I test matrix except that the last series using I3 will be substituted with J2 (.0010) & K3 (.0080). A decision will be made regarding low Reynolds Number (.70). We expect to get air around 12:00 PM.

**12:00 PM** - Problem gage #30 has suddenly occurred, the recorded data looks good but the current data is erratic. The plant has no electricity and will be delayed for several hours. The pitot tube will cause interference problems with the sting if the model is inverted, which is planned sometime today. It has therefore been decided to take it out of the tunnel.

**3:00 PM** - Cooling manifold was removed in preparation for a planned inverted run.

**3:16 PM** - Air is turned on, expected to run within 1 hour.

**4:09 PM** - First shift (Run #50) repeat of Run #49 which had a dew point problem.

**4:43 PM** - Three consecutive runs were made to make an effort to determine why the flow is not laminar at the lower Reynolds numbers. Run #53 was a repeat of Run #52 (Re = 1.00 & hot wall) except that the angle of attack was reduced to 35°. The flow was completely laminar for the first time of the test. The next run, the angle of attack was increased to 43°. The separation was worse than at 40°. The model was inverted 180° (model angle = 40°) to determine if the early separation was caused by a problem related to the open doors below the model. The test

### **Table 7. Continued**

showed separation was identical to that of the +40° angle data (run #52)> It is unknown what causes the early separation, but the tunnel is symmetrical and is not a cause. Scott Berry of NASA/LaRC suspects a reflected shock is causing the anomaly.

**5:00 PM** - Cooling manifold was re-attached to get ready for the next cold runs. The model was inspected and is in excellent condition. The t/c's are not moving around.

**6:26 PM** - Model change #3 was made and took 17 minutes. D3 was replaced with D1 and G1 was replaced with G3. Model was inspected and looked good. The screw holes for J (left) and I (right) were refilled.

**6:58 PM** - Because of the success of the reduced angle of attack, the next series (perhaps all the series following) will run an angle of attack sweep (35°, 38°, 40°).

**8:00 PM** - Currently we have made 22 runs (62 total) at a rate of 5.74 runs/hr.

**9:15 PM** - Model change #4, G3 changed to G1 and B1C1 changed to B1C3. The change took 10 minutes. Inspection of model showed that the model is holding up well and nothing is apparently moving around. Use of heat gun to warm model is very helpful as a sheet of ice rapidly builds up after model comes out of flow.

**9:57 PM** - Have now completed 28 runs this shift (68 total 40% of test) 5.64 runs /hr and have been running for 4 hrs and 58 minutes this shift.

**11:15 PM** - Made model change #5, replaced B1C3 with B1C1, replaced J1 with J2 and replaced K1 with K3. The change took 15 minutes. Model inspection revealed that the filler for element G had largely fallen out and was repaired. This series will be the final one of Phase I.

**11:35 PM** - Made a repair to screw hole filler for K - left screw, G - left screw, and both on J. The repair took 10 minutes. We believe that the model was too cold when the previous change was made. Extra effort needs to be made to keep the model at a warmer temperature.

### **Friday June 9, 1995**

**1:40 AM** - Final run of shift, 55 runs (95 total - 53.4% of test), 5.84 runs/hr. From first run to last run the delta time was 9 hrs and 25 min.

**10:AM** - Made a detailed inspection of model, the left screw filler for element A has fallen out. A decision has been made to move the oil flow runs to earlier in the test today. We will be spraying the lower surface with Dykem instead of paint. Carl Kidd has informed us that this will not be a problem for the gages.

## Table 7. Continued

**12:40 PM** - Repaired the left hole of element A and sprayed the lower surface with dark blue Dykem. Ken Nutt has changed the model center of rotation so that the model will be 1" higher in the tunnel during injection. This is an effort to minimize the effect of a suspected shock which may be impinging on the aft end of the Orbiter. We have moved the cooling manifold up closer to the model much like it was prior to the center of rotation change.

**1:00PM** - Model was inverted and injected into the tunnel so that the photographer can focus his camera prior to the oil flow runs. We expect to get the tunnel running as soon as the photographer is done.

**2:08 PM** - Tunnel is on-line.

**2:40 PM** - First run of day. The increased height of model has apparently solved the transition problem at lower Reynolds Number in the .8 X/L location. A shock off the doors is probably the cause.

**3:51 PM** - Completed first series of runs (54 minutes). Model change #6 going to all smooth. A new procedure was used; the elements are changes and the model is re-inserted to warm the model prior to applying the dental plaster. The temperature should be roughly room temperature for the dental plaster to stay in the holes. J2 was changed to J1 and K3 was changed to K1. The change including the reinsertion took 20 minutes. Dykem is almost completely gone, model preparation for spraying was poor.

**4:30 PM** - New method of filling screw holes is holding up well.

**5:45 PM** - Left hole filler of element A fell out. This one fell out at the end of last night. Model was heated in tunnel and then hole was refilled. This fix took 5 minutes. Currently we are averaging 5.5 runs/hr and have 19 good runs.

**7:10 PM** - Overheating problems in the heaters are preventing us from running at the higher Reynolds Number. We are going to drop down to the lower Reynolds Numbers while we adjust the cooling manifold closer to the model. The manifold is further away than last night and frost is becoming a big problem. It is important that the manifold is 2 inches from the model. The change took approximately 30 minutes and the manifold is 2 inches from the lower surface and the front of the manifold is about 1 inch further forward than the Orbiter nose, like it was yesterday.

**8:00 PM** - Pits developed in the fillers for elements A, BC, & D. Problems in data revealed the problem. We made several high Reynolds number (3.50), this could be a source of the problem. It may be that the filler in front of the model needs to be "serviced" every few runs.

**8:30 PM** - Model change #7; replaced B1C1 with B1C4. The change took 10 minutes. It was unnecessary to heat the model in the tunnel because the nose is easily heated by a heat gun.

### **Table 7. Concluded**

**9:40 PM** - Re-Dykem model in preparation for oil flows. 4 oil flow runs were made and produced streamlines consistent with transition on one side and laminar on the other. The best technique for applying the oil was to apply tiny blotches with a sponge.

**10:40 PM** - Made model change #8; replaced B1C4 with B1C1 and A1 was replaced with A2. The change took 15 minutes and included re-inverting the model.

#### **Saturday June 10, 1995**

**12:07 AM** - Made model change (10 minutes), changed A2 with A1 and replaced F1 with F3. Pressure problems in cooling system make any further cold wall runs on this shift impossible. Only hot wall tests will be run for the remainder of shift.

**12:54 AM** - Made model change; replaced F3 with F1 and replaced G1 with G2. The change took 10 minutes.

**1:20 AM** - Center of rotation changed to the original one we had at the beginning of test for final run which will be a temperature / time.

**1:27 AM** - Official end of test, 150 runs, 34 hrs 1 min of actual run time (summation of time of first run to time of last run each shift).

**1:48 AM** - Actual end of test, two extra runs were run as tunnel was being brought down.

**Table 8 - Summary of Good Data Runs**

**Table 9. List of Runs Not Utilized and Reasons Why**

1. **Runs 1 - 13:** Data corrupted due to unintentional roughness at Element G screw-hole filler and possibly B, C, and F. Also, gages 34 and 23 were sanded smooth after Run 13.
2. **Run 15:** Excessive frost on model.
3. **Run 17:** Excessive frost on model.
4. **Run 19:** Possible frost on model.
5. **Run 22:** Possible frost on model.
6. **Run 34:** Excessive frost on model.
7. **Run 38:** No data taken.
8. **Run 41:** Filler fell out of Element A.
9. **Run 43:** No data taken.
10. **Run 46:** Data problems, but may be good data.
11. **Run 47:** Model was not isothermal.
12. **Run 49:** Tunnel dew point was high.
13. **Run 55:** Data probably good. Model was rolled 180°.
14. **Run 82:** Data probably good. Wrong punch code was entered.
15. **Run 86:** Possible frost on model.
16. **Run 91:** Filler fell out of Elements G, J, and K.
17. **Runs 101 - 108:** Possible frost problems on model.
18. **Run 115:** Special run for obtaining temp. history data for interference shock check.
19. **Run 127:** Filler fell out of left side of Element A.
20. **Runs 130 - 132:** Possible frost on model.
21. **Run 135:** Excessive frost on model.
22. **Run 136:** Filler on Element A damaged.
23. **Runs 145 - 149:** Oil flow runs.
24. **Runs 166 - 167:** Data questionable.

## **APPENDIX A**

### **Comparison of Predicted Laminar Heat Transfer Coefficient Distribution With MH-11 Measurements**

**This page intentionally left blank**

(

Measured (MH-11) and Computed  $h/h_{ref}$  on Orbiter Windward Surface

$Re/ft=3.580E+06$ ;  $T_w/T_o=0.374$ ;  $\alpha=40.0$

Smooth Body

**Run #116**

Figure A-1. - Comparison of Predicted Laminar Heat Transfer Coefficient Distribution with MH-11 Measurements.

13. ABSTRACT ( <i>Maximum 200 words</i> ) Several Space Shuttle Orbiter flights have experienced earlier than expected laminar to turbulent boundary layer transition. Such an experience has often been asymmetric in nature, which results in unplanned control requirements and often higher localized heating. It was typically noted that evidence of roughness elements, such as thermal protection system (TPS) gap fillers protruding above the surrounding surface, was generally a common factor for the flights experiencing the unexpected early transition. We conducted a test in the Arnold Engineering and Development Center's Von Karman Facility Tunnel B to determine the effect of specific discrete roughness element heights and locations on the transition of the Orbiter boundary layer from laminar to turbulent at various Reynolds numbers. We limited angle of attack to 35 and 40 degrees, which are most representative of the flight experience. The major objectives of the test were to verify that off-design changes, such as protuberances, to the TPS could cause roughness-induced early transition consistent with flight experience and to determine which sizes and locations of roughness elements would cause early transition. Test results indicate that, while a single roughness element on the windward centerline near the nose region could induce early transition over most of the windward surface, a single roughness element off to the side of the windward centerline could result in a turbulent boundary layer occurring on a major portion of one side of the windward surface with the other side remaining laminar. Both increasing the height of the roughness element on the windward centerline and cooling the model resulted in transition at lower freestream Reynolds numbers.
