# Stopping Sets

- Definition: a set of variable nodes  $\Rightarrow$  the induced graph contains no check node of degree 1.

# Stopping Sets

- Definition: a set of variable nodes  $\Rightarrow$  the induced graph contains no check node of degree 1.

- Why **exhaustive search** algorithms (for small stopping sets)?

# Stopping Sets

- Definition: a set of variable nodes  $\Rightarrow$  the induced graph contains no check node of degree 1.

- Why **exhaustive search** algorithms (for small stopping sets)?
  - Error floor optimization. BECs vs. non-erasure channels.

# Stopping Sets

- Definition: a set of variable nodes  $\Rightarrow$  the induced graph contains no check node of degree 1.

- Why **exhaustive search** algorithms (for small stopping sets)?
  - Error floor optimization. BECs vs. non-erasure channels.
- Good but **inexhaustive** search algorithms: error floors of LDPC codes [Richardson 03], projection algebra [Yedidia *et al.* 01], the approximate minimum distance of LDPC codes [Hu *et al.* 04], [Hiroto *et al.* 05], [Richter 06]

# An NP-Hard Problem

=== The  $SD(H, t)$  problem ===

**INPUT:** A code represented by its parity-check matrix  $H$  and an integer  $t$ .

**OUTPUT:** Output 1 if the minimal stopping distance of  $H$  is  $\leq t$ .  
Otherwise, output 0.

## The hardness results:

- [Krishnan *et al.* 06]: For arbitrary  $H$ ,  $SD(H, t)$  is NP-complete.  
Proof: By reducing a VERTEX-COVER problem to  $SD(H, t)$ .
- A byproduct of [Krishnan *et al.* 06]: With the sparsity restriction that the number of 1's in  $H$  is limited to  $O(n)$  rather than  $O(n^2)$ , then  $SD(H, t)$  is still NP-complete.

# Trapping Sets: Definitions

- **Operational definition:** “the set of bits that are **not eventually correct**” [Richardson 03].

# Trapping Sets: Definitions

- **Operational definition:** “the set of bits that are **not eventually correct**” [Richardson 03].
- **Empirical observations:** For non-erasure channels: trapping sets are  $(a, b)$  near-codeword [MacKay *et al.* 03]

# Trapping Sets: Definitions

- **Operational definition:** “the set of bits that are **not eventually correct**” [Richardson 03].
- **Empirical observations:** For non-erasure channels: trapping sets are  $(a, b)$  near-codeword [MacKay *et al.* 03]
  - **$(a, b)$  near codeword:** A set of  $a$  variable nodes such the induced graph has  $b$  **odd-degree** check nodes.

# Trapping Sets: Definitions

- **Operational definition:** “the set of bits that are **not eventually correct**” [Richardson 03].
- **Empirical observations:** For non-erasure channels: trapping sets are  $(a, b)$  near-codeword [MacKay *et al.* 03]
  - **$(a, b)$  near codeword:** A set of  $a$  variable nodes such the induced graph has  $b$  **odd-degree** check nodes.
  - A  $(a, 0)$  near codeword  $\not\Leftarrow$  a stopping set  
 $\Rightarrow$

# Trapping Sets: Definitions

- **Operational definition:** “the set of bits that are **not eventually correct**” [Richardson 03].
- **Empirical observations:** For non-erasure channels: trapping sets are  $(a, b)$  near-codeword [MacKay *et al.* 03]
  - **$(a, b)$  near codeword:** A set of  $a$  variable nodes such the induced graph has  $b$  **odd-degree** check nodes.
  - A  $(a, 0)$  near codeword  $\begin{matrix} \not\Leftarrow \\ \Rightarrow \end{matrix}$  a stopping set
- We propose a new graph-theoretic definition:  
**Definition 1 (  $k$ -out Trapping Sets )** A subset of  $\{v_1, \dots, v_n\}$  such that in **the induced subgraph**, there are exactly  $k$  **check nodes of degree one**.

# $k$ -Out Trapping Sets vs. Near-Codeword

**Definition 1 (  $k$ -out Trapping Sets )** *A subset of variables such that in the induced subgraph, there are exactly  $k$  check nodes of degree one.*

- $k$ -out trapping sets  $\longleftrightarrow$  stopping sets  
 $(a, b)$  near-codewords  $\longleftrightarrow$  valid codewords
- 0-out trapping sets  $\iff$  stopping sets  
 $(a, 0)$  near-codewords  $\iff$  valid codewords

# $k$ -Out Trapping Sets vs. Near-Codeword

**Definition 1 (  $k$ -out Trapping Sets )** *A subset of variables such that in the induced subgraph, there are exactly  $k$  check nodes of degree one.*

- $k$ -out trapping sets  $\longleftrightarrow$  stopping sets  
 $(a, b)$  near-codewords  $\longleftrightarrow$  valid codewords
- 0-out trapping sets  $\iff$  stopping sets  
 $(a, 0)$  near-codewords  $\iff$  valid codewords

Why this definition?

# $k$ -Out Trapping Sets vs. Near-Codeword

**Definition 1 (  $k$ -out Trapping Sets )** *A subset of variables such that in the induced subgraph, there are exactly  $k$  check nodes of degree one.*

- $k$ -out trapping sets  $\longleftrightarrow$  stopping sets  
 $(a, b)$  near-codewords  $\longleftrightarrow$  valid codewords
- 0-out trapping sets  $\iff$  stopping sets  
 $(a, 0)$  near-codewords  $\iff$  valid codewords

Why this definition?

- Better analogy to stopping sets.

# $k$ -Out Trapping Sets vs. Near-Codeword

**Definition 1 (  $k$ -out Trapping Sets )** A subset of variables such that in the induced subgraph, there are exactly  $k$  check nodes of degree one.

- $k$ -out trapping sets  $\longleftrightarrow$  stopping sets  
 $(a, b)$  near-codewords  $\longleftrightarrow$  valid codewords
- 0-out trapping sets  $\iff$  stopping sets  
 $(a, 0)$  near-codewords  $\iff$  valid codewords

Why this definition?

- Better analogy to stopping sets.
- An  $(a, b)$  near-codeword  $\not\iff$  “ $k \leq b$ ”-out trapping set.  
 $\implies$
- Our goal: With fixed  $b$ , search all min.  $k \leq b$ -out TSs.

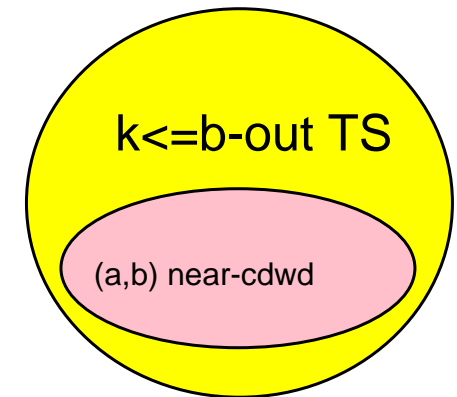

# $k$ -Out Trapping Sets vs. Near-Codeword

**Definition 1 (  $k$ -out Trapping Sets )** A subset of variables such that in the induced subgraph, there are exactly  $k$  check nodes of degree one.

- $k$ -out trapping sets  $\longleftrightarrow$  stopping sets  
( $a, b$ ) near-codewords  $\longleftrightarrow$  valid codewords
- 0-out trapping sets  $\iff$  stopping sets  
( $a, 0$ ) near-codewords  $\iff$  valid codewords

Why this definition?

- Better analogy to stopping sets.
- An ( $a, b$ ) near-codeword  $\begin{matrix} \nleftrightarrow \\ \Rightarrow \end{matrix}$  " $k \leq b$ "-out trapping set.
- Our goal: With fixed  $b$ , search all min.  $k \leq b$ -out TSs.
- Empirically, all error bits consist of only degree 1 & 2 check nodes. (The elementary trapping set [Landner *et al.* 05].)

# The Hardness of $k$ -OTD( $H, t$ )

=== The  $k$ -OTD( $H, t$ ) problem ===

**INPUT:** A code represented by its parity-check matrix  $H$  and an integer  $t$ .

**OUTPUT:** Output 1 if the minimal  $k$ -out trapping distance of  $H$  is  $\leq t$ . Otherwise, output 0.

# The Hardness of $k$ -OTD( $H, t$ )

=== The  $k$ -OTD( $H, t$ ) problem ===

**INPUT:** A code represented by its parity-check matrix  $H$  and an integer  $t$ .

**OUTPUT:** Output 1 if the minimal  $k$ -out trapping distance of  $H$  is  $\leq t$ . Otherwise, output 0.

- When  $k = 0$ , then  $0$ -OTD( $H, t$ ) = SD( $H, t$ ) is NP-complete.

# The Hardness of $k$ -OTD( $H, t$ )

=== The  $k$ -OTD( $H, t$ ) problem ===

**INPUT:** A code represented by its parity-check matrix  $H$  and an integer  $t$ .

**OUTPUT:** Output 1 if the minimal  $k$ -out trapping distance of  $H$  is  $\leq t$ . Otherwise, output 0.

- When  $k = 0$ , then  $0$ -OTD( $H, t$ ) = SD( $H, t$ ) is NP-complete.
- Is the hardness the same for any fixed  $k > 0$  values?

# Our First Result

**Theorem 1** Consider a fixed  $k > 0$ . For arbitrary  $H$ ,  $k$ -OTD( $H, t$ ) is *NP-complete*.

**Theorem 2** Consider a fixed  $k > 0$ . With the *sparsity restriction* that the number of 1's in  $H$  is limited to  $O(n)$  rather than  $O(n^2)$ , then  $k$ -OTD( $H, t$ ) is *still NP-complete*.

Proof: Reduction from SD( $H, t$ ).

# SD( $H, t$ ) By $k$ -OTD( $H', t'$ )

Step 1: Duplicate  $G$  ( $k + 2$ ) times

$$k = 2$$

# SD( $H, t$ ) By $k$ -OTD( $H', t'$ )

Step 1: Duplicate  $G$  ( $k + 2$ ) times

$k = 2$

# SD( $H, t$ ) By $k$ -OTD( $H', t'$ )

Step 1: Duplicate  $G$  ( $k + 2$ ) times

$k = 2$

# SD( $H, t$ ) By $k$ -OTD( $H', t'$ )

Step 1: Duplicate  $G$  ( $k + 2$ ) times

$k = 2$

# SD( $H, t$ ) By $k$ -OTD( $H', t'$ )

Step 1: Duplicate  $G$  ( $k + 2$ ) times

$k = 2$

Run  
 $k$ -OTD( $H', t(k + 2)$ ).

Claim:

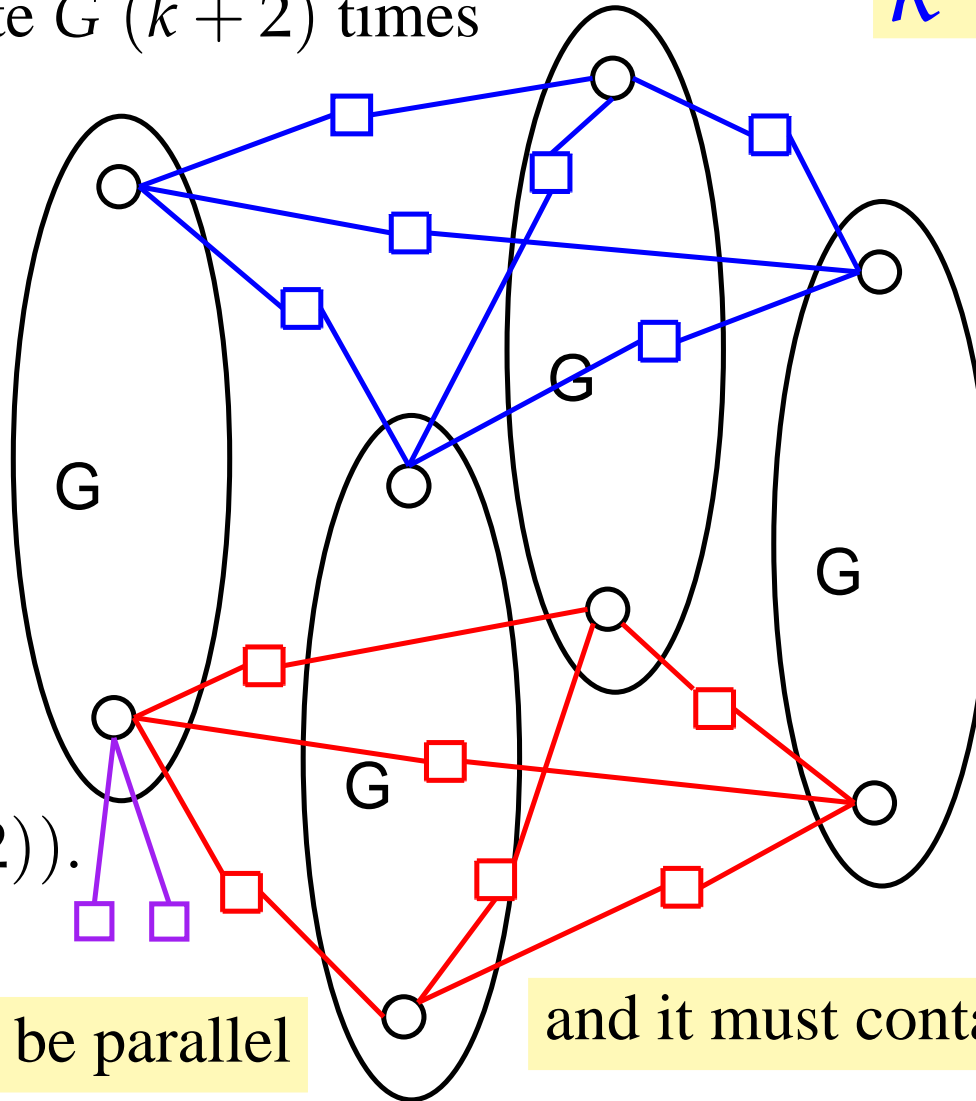

any  $k$ -out TS must be parallel

# SD( $H, t$ ) By $k$ -OTD( $H', t'$ )

Step 1: Duplicate  $G$  ( $k + 2$ ) times

$k = 2$

Run  
 $k$ -OTD( $H', t(k + 2)$ ).

Claim:

any  $k$ -out TS must be parallel

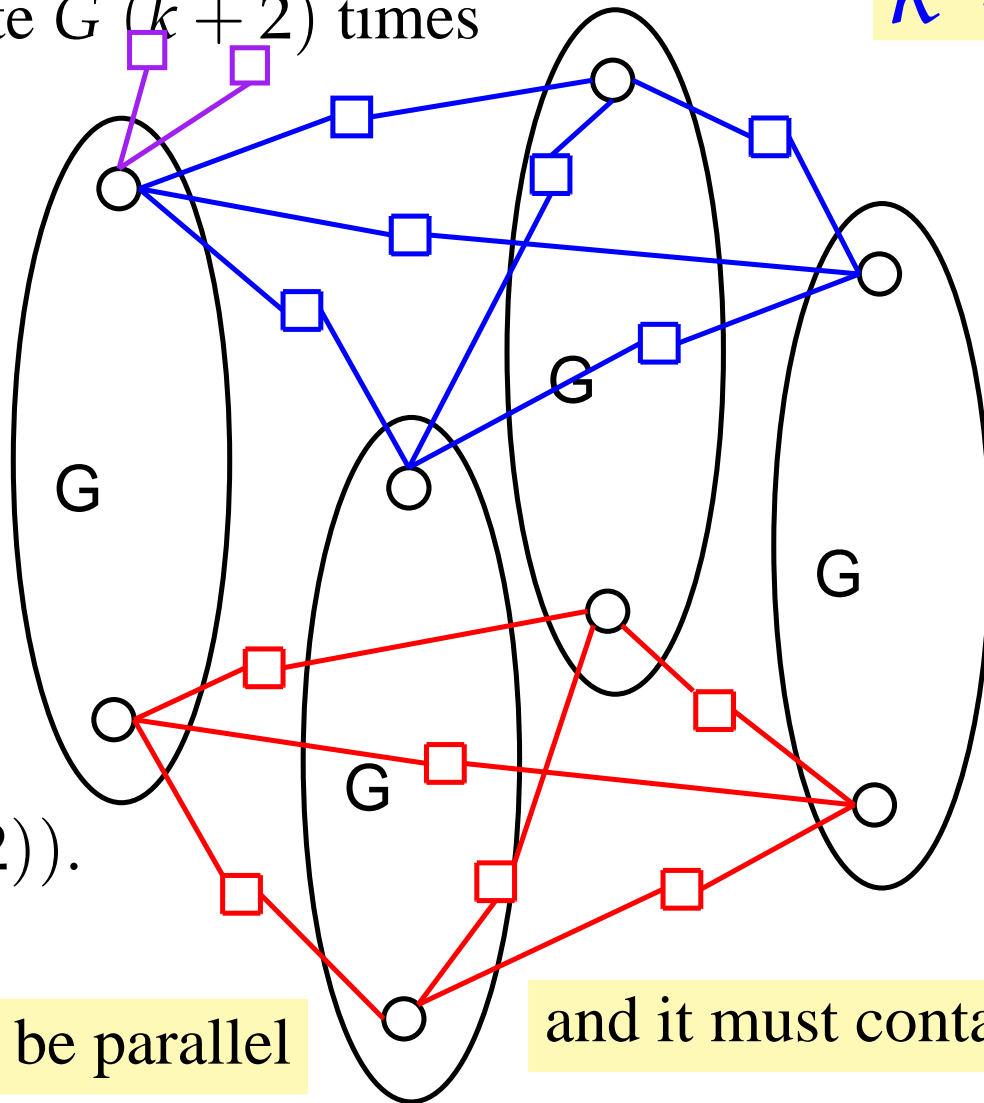

and it must contain the target bit.

# SD( $H, t$ ) By $k$ -OTD( $H', t'$ )

$k = 2$

Step 1: Duplicate  $G$  ( $k + 2$ ) times

Run  $k$ -OTD( $H', t(k + 2)$ ).

Claim:

any  $k$ -out TS must be parallel

and it must contain the target bit.

# NP-hard problem = Impossible?

# NP-hard problem = Impossible?

- Most approaches use **heuristics** instead for error-floor optimization.
  - The girth, the Approximate Cycle Extrinsic (ACE) message degree, partial stopping set elimination, and ensemble-inspired upper bounds.

# NP-hard problem = Impossible?

- Most approaches use **heuristics** instead for error-floor optimization.
  - The girth, the Approximate Cycle Extrinsic (ACE) message degree, partial stopping set elimination, and ensemble-inspired upper bounds.

Is there anything else we can do?

# NP-hard problem = Impossible?

- Most approaches use **heuristics** instead for error-floor optimization.
  - The girth, the Approximate Cycle Extrinsic (ACE) message degree, partial stopping set elimination, and ensemble-inspired upper bounds.

Is there anything else we can do?

- NP-completeness  $\implies$  the **asymptotic complexity**.

# NP-hard problem = Impossible?

- Most approaches use **heuristics** instead for error-floor optimization.
  - The girth, the Approximate Cycle Extrinsic (ACE) message degree, partial stopping set elimination, and ensemble-inspired upper bounds.

Is there anything else we can do?

- NP-completeness  $\implies$  the **asymptotic complexity**.
- NP-completeness has relatively less predictability for finite  $n$ .

# NP-hard problem = Impossible?
